

UNDERSTAND, DESCRIBE AND EXPLAIN:

Learning links:

Pupils should be taught to:

Identify how sounds are made, associating some of them with something vibrating

Recognise that vibrations from sounds travel through a medium to the ear

Find patterns between the pitch of a sound and features of the object that produced it

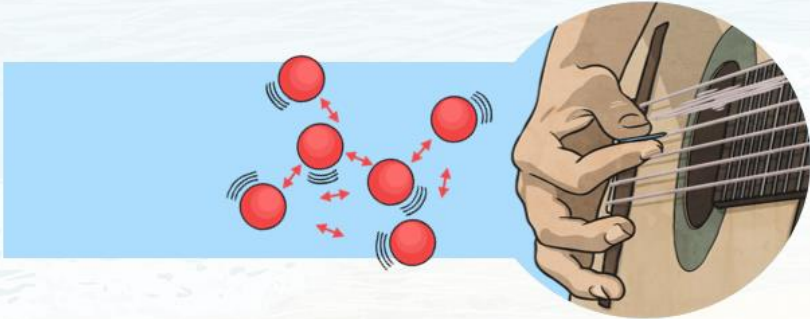

Find patterns between the volume of a sound and the strength of the vibrations that produced it.

Recognise that sounds get fainter as the distance from the sound source increases

vibrate	sound		louder		Eat protectors		tines		cochlea	
vibration	volume		string		frequency		Tuning fork			
vibrating	pitch		percussion		Finger board		Wind instrument			
air	medium	faint	brass	fret	guiro	pinna	stirrup			
ear	fainter		woodwind		Sound wave		Eardrum			
hear	loud		insulate		Stringed instrument					

How Sound is Made

- Like light, sound travels through the air in waves.
- Sound is made by air molecules vibrating.
- When you clap your hands, the air around your hands shakes. This is the air molecules vibrating.

Molecules Vibrating

When air molecules inside the ear vibrate, they shake tiny hairs on the insides of the ears. The hairs are connected to nerves under the skin.

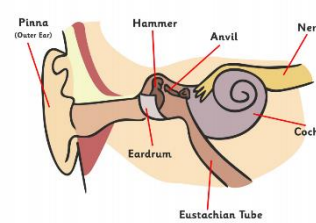

Communicating with the brain

These nerves send messages to your brain to tell you that you heard a noise.

Have you ever felt a speaker when the sound is on?

It vibrates.

THE EAR

THINKING POINT:

HOW IS SOUND SIMILAR TO LIGHT?

EXPLORE AND INVESTIGATE:

Sound needs molecules to move. It is impossible for sound to travel in space.

Sound doesn't have to move through air. It can travel through water or metal.

In fact, sound travels faster through water and solids than it does through air.

Sound travels much slower than light, whether in air or in water.

You often hear things after you see them, for example you see the lightning before you hear the thunder.

Light travels at 186,000 miles per second. Sound travels at 770 miles per hour.

Whenever we talk about sound and pitch, we're talking about if the sound is a high sound or a low sound.

For example, if we described a referee's whistle being blown, you could say it has a high pitch because the sound makes a high screeching sound.

If we described a large drum being beaten, you could say it has a low pitch because the sound makes a low thudding sound.

THINKING POINT:

How are the vibrations from a loud sound different from the vibrations of a soft sound?

HYPOTHESISE
ENQUIRE
TEST
RECORD
REPORT
CONCLUDE

Sounds get quieter as the distance between the sound source and your ear increases.

Sounds travel as vibrations. As the sound waves travel, the particles of whatever they are travelling through vibrate, or move quickly on the spot. The further the vibrations travel, the more they spread out. As they spread out through more and more particles, the vibrations become smaller and smaller. This causes the sound to get quieter and quieter.

Think of dropping a leaf into a pond. The very first ripples directly around the leaf will be very large, but as the ripples spread out across the pond, they will get smaller and smaller until eventually they disappear.

This is why sounds get quieter and quieter as you move further away from the source, until you eventually can't hear the sound at all.

You can see the ripples getting smaller as they spread out across the pond, until they eventually disappear. This is like the way the vibrations of sound get smaller as they spread out over distance, getting quieter and quieter.

Sounds also get quieter over distance because some of the vibrations are absorbed by obstacles they meet.

If the ripples in the pond below hit an obstacle such as a stick or rock, they would not travel as far. This can help you understand why sounds get quieter as you move further away.

Telephones are used to transmit the sound of people's voices over long distances.

When you speak into a telephone, the sound energy in your voice is turned into electrical energy, which is transported down a wire to the other person's telephone. The electrical energy is converted back into sound energy, and they can hear what you are saying!

What You Need

- An empty drinking bottle
- A metal spoon
- Pouring jug
- Water

What to Do

- 1 Fill your bottle about half full of water using the pouring jug - take care not to spill it!
- 2 Now with the metal spoon, strike the side of the bottle and listen to the sound that you hear come out of the top of the bottle. How would you describe that sound? High pitched or low pitched?
- 3 Using the same bottle fill it up a little further, about $\frac{3}{4}$ full
- 4 Now strike the bottle again using the metal spoon, and listen carefully to the sound that you get this time.

Here's What's Happening...

When you strike the bottle, you are causing vibrations and this is what causes sound.

When the bottle is almost full, the glass vibrates slowly. This is because as the vibrations travel, the water slows them down.

This makes a low pitch.

When the bottle is only half full, the glass is able to vibrate much quicker. This is because there is less water to slow the vibrations down.

This makes a high pitch.

Experiment with the water and you'll see that you can make all sorts of sounds and even maybe play a tune!

KEY ASSESSMENT AND APPLICATION OPPORTUNITIES:

EXS:

1. Explain why some sounds are high and others low?

GDS:

1. What conclusions can you draw from the fact whales can communicate over hundreds of miles?
